UCL Finance Seminar
14 October 2026

The views expressed are those of the authors and do not necessarily reflect those of the BIS.

Government bonds as a hedge

- A government bond is safe when it appreciates in bad states of the world
  (Brunnermeier, Merkel, and Sannikov 2024; Gómez-Cram, Kung, and Lustig 2024)
- Investors price the hedge: forecasters expect higher returns on bonds that move with stocks
  (Leombroni, Pflueger, and Sunderam 2026)
- The hedge is commonly measured by the stock-bond correlation:

$$\rho^{sb}_{i,t} = \text{corr}\left(r^{\text{equity}}_{i,t},\ r^{\text{bond}}_{i,t}\right) \qquad \begin{cases} \rho^{sb} < 0 & \text{bonds hedge equity risk} \\ \rho^{sb} > 0 & \text{stocks and bonds fall together} \end{cases}$$

- **Literature so far:** in the US, monetary policy and procyclical inflation explain the hedge
  (Campbell, Sunderam, and Viceira 2017; Song 2017; Campbell, Pflueger, and Viceira 2020)
- **This paper:** is a government's fiscal capacity a determinant of the hedge?

The euro area before 2010

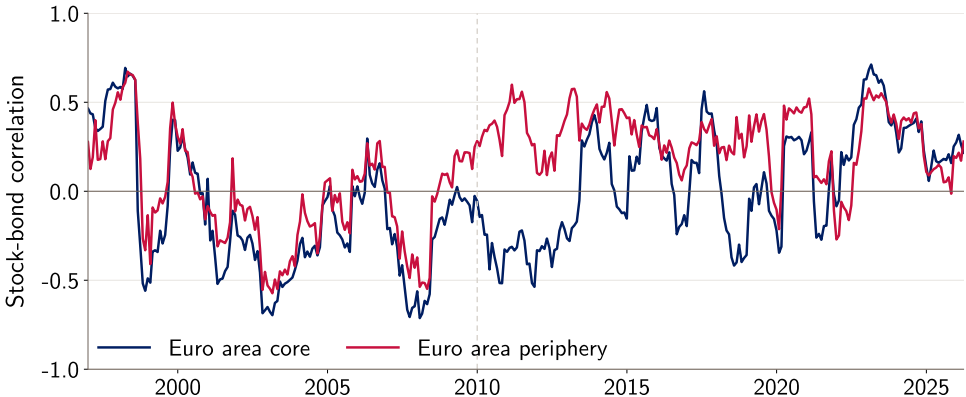

One central bank, one currency, one inflation target: core and periphery move together.

The euro area from 2010

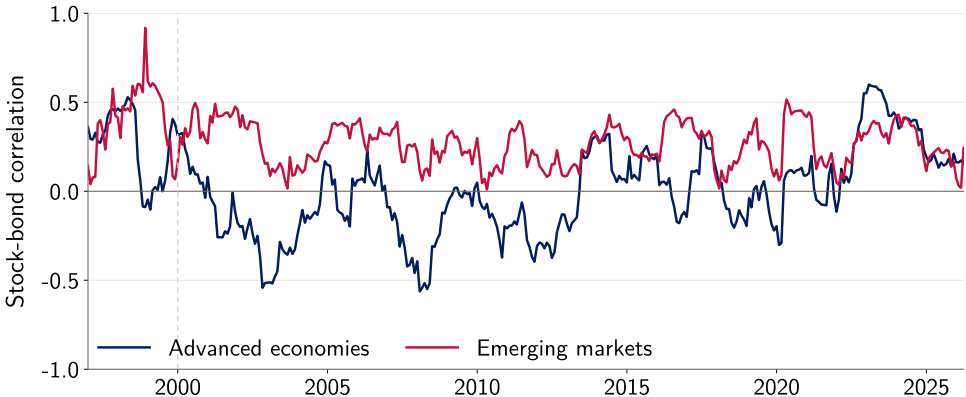

During the sovereign debt crisis the periphery loses the hedge; the core keeps it.

Convergence above zero

Since 2022 the core has joined the periphery above zero: neither keeps the hedge.

Advanced and emerging markets

After 2000 advanced economies gained the hedge; emerging markets did not.

What we find

Question: does weaker fiscal capacity erode the hedge that government bonds provide?

- **Across countries:** countries with a higher interest bill have bonds that hedge less
- **Within countries:** as a country's interest bill rises, its bonds hedge less
- **Euro area:** after the Greek deficit revision the periphery-core gap rises by 0.44
- **Fiscal news:** the hedge weakens after the press writes more about fiscal sustainability
- **Rating actions:** the hedge weakens in the month of a fiscal downgrade
- **Channel:** within countries, default risk carries it; real rates and breakeven inflation do not

Conclusion

Environment

One productivity shock, with volatility σ and persistence $\rho > 0$:

$$Y_{t+1} = Y_t \exp(g + \rho\sigma\varepsilon_t + \sigma\varepsilon_{t+1}), \qquad \varepsilon_t \sim \mathcal{N}(0,1) \text{ i.i.d.}$$

- A positive realization raises current output and expected next-period growth
- Log utility with discount factor δ; the household consumes the endowment, $C_t = Y_t$

The government collects taxes $\tau\, Y_t$ at a fixed rate and rolls over one-period nominal debt

- Fiscal capacity is limited: it repays at most a share $\lambda < 1$ of the present value of its taxes
- Monetary dominance: beyond that limit it defaults; inflation stays at the target $\bar{\pi}$
- Fiscal dominance: no default; a price-level jump erodes the nominal debt to the limit
- Superscript n marks nominal values: the rate i_t^n, debt B_t^n, output Y_t^n

Environment

One productivity shock, with volatility σ and persistence $\rho > 0$:

$$Y_{t+1} = Y_t \exp(g + \rho\sigma\varepsilon_t + \sigma\varepsilon_{t+1}), \qquad \varepsilon_t \sim \mathcal{N}(0,1) \text{ i.i.d.}$$

- A positive realization raises current output and expected next-period growth
- Log utility with discount factor δ; the household consumes the endowment, $C_t = Y_t$

The government collects taxes $\tau\, Y_t$ at a fixed rate and rolls over one-period nominal debt

- Fiscal capacity is limited: it repays at most a share $\lambda < 1$ of the present value of its taxes
- Monetary dominance: beyond that limit it defaults; inflation stays at the target $\bar{\pi}$
- Fiscal dominance: no default; a price-level jump erodes the nominal debt to the limit
- Superscript n marks nominal values: the rate i_t^n, debt B_t^n, output Y_t^n

The safe-haven channel

Bonds, through the real rate

$$\log(1 + r_t) = -\log\delta + g + \rho\sigma\varepsilon_t - \tfrac{1}{2}\sigma^2$$

- Bad news lowers expected growth and the real rate, so the bond price rises

Stocks, through output

$$\frac{\partial \log p_t}{\partial \varepsilon_t} = \sigma > 0$$

- Bad news lowers output, and with it the equity price

$\Rightarrow$ Bonds rise while stocks fall, so bonds hedge $\rightarrow$ safe-haven channel

Why persistent shocks

The safe-haven channel

Bonds, through the real rate

$$\log(1 + r_t) = -\log \delta + g + \rho\sigma\varepsilon_t - \tfrac{1}{2}\sigma^2$$

- Bad news lowers expected growth and the real rate, so the bond price rises

Stocks, through output

$$\frac{\partial \log p_t}{\partial \varepsilon_t} = \sigma > 0$$

- Bad news lowers output, and with it the equity price

$\Rightarrow$ Bonds rise while stocks fall, so bonds hedge $\rightarrow$ safe-haven channel

Why persistent shocks

The safe-haven channel

Bonds, through the real rate

$$\log(1 + r_t) = -\log \delta + g + \rho\sigma\varepsilon_t - \tfrac{1}{2}\sigma^2$$

- Bad news lowers expected growth and the real rate, so the bond price rises

Stocks, through output

$$\frac{\partial \log p_t}{\partial \varepsilon_t} = \sigma > 0$$

- Bad news lowers output, and with it the equity price

$\Rightarrow$ Bonds rise while stocks fall, so bonds hedge $\rightarrow$ safe-haven channel

Why persistent shocks

The fiscal-capacity channel

Default when liabilities exceed what the government can repay:

$$\xi_t = \mathbf{1}\{\lambda A_t < L_t\}$$

- L_t: real liabilities entering t; A_t: the present value of all future taxes
- In default the government repays λA_t, a share $\lambda < 1$ of that value

Default at $t+1$ when $\varepsilon_{t+1} < z_t$, with threshold

$$z_t = \frac{1}{\sigma}\Bigg[\log \underbrace{\frac{(1+i_t^n)\,B_t^n}{Y_t^n}}_{\text{forward interest expense}} - \log \underbrace{\frac{(1+\bar{\pi})\,\lambda\,\tau}{1-\delta}}_{\substack{\text{fiscal capacity} \\ \text{per unit of output}}} - g - \rho\sigma\varepsilon_t\Bigg]$$

- Bad news raises the debt rolled over relative to output: default becomes more likely

$\Rightarrow$ Bonds fall with stocks, so the hedge weakens $\rightarrow$ fiscal-capacity channel

The fiscal-capacity channel

Default when liabilities exceed what the government can repay:

$$\xi_t = \mathbf{1}\{\lambda A_t < L_t\}$$

- L_t: real liabilities entering t; A_t: the present value of all future taxes
- In default the government repays λA_t, a share $\lambda < 1$ of that value

Default at $t+1$ when $\varepsilon_{t+1} < z_t$, with threshold

$$z_t = \frac{1}{\sigma}\left[\log \underbrace{\frac{(1+i_t^n)\,B_t^n}{Y_t^n}}_{\text{forward interest expense}} - \log \underbrace{\frac{(1+\bar{\pi})\,\lambda\,\tau}{1-\delta}}_{\substack{\text{fiscal capacity} \\ \text{per unit of output}}} - g - \rho\sigma\varepsilon_t\right]$$

- Bad news raises the debt rolled over relative to output: default becomes more likely

$\Rightarrow$ Bonds fall with stocks, so the hedge weakens $\rightarrow$ fiscal-capacity channel

The fiscal-capacity channel

Default when liabilities exceed what the government can repay:

$$\xi_t = \mathbf{1}\{\lambda A_t < L_t\}$$

- L_t: real liabilities entering t; A_t: the present value of all future taxes
- In default the government repays λA_t, a share $\lambda < 1$ of that value

Default at $t+1$ when $\varepsilon_{t+1} < z_t$, with threshold

$$z_t = \frac{1}{\sigma}\left[\log \underbrace{\frac{(1+i_t^n)\,B_t^n}{Y_t^n}}_{\text{forward interest expense}} - \log \underbrace{\frac{(1+\bar{\pi})\,\lambda\,\tau}{1-\delta}}_{\substack{\text{fiscal capacity} \\ \text{per unit of output}}} - g - \rho\sigma\varepsilon_t\right]$$

- Bad news raises the debt rolled over relative to output: default becomes more likely

$\Rightarrow$ Bonds fall with stocks, so the hedge weakens $\rightarrow$ fiscal-capacity channel

Two channels

The bond's equity beta

$$\beta_t \equiv \frac{\mathrm{Cov}_t(\log q_{t+1},\, \log p_{t+1})}{\mathrm{Var}_t(\log p_{t+1})}$$

has the sign of the stock-bond correlation ρ_t^{sb}.

Propositions 1 and 2 (fiscal dominance adds a third term, $\Phi(z_t)$)

$$\beta_t = \underbrace{\mathbb{E}_t[(1-\xi_{t+1})\,\Theta_{t+1}\,(1+\tau Y_{t+1}/B_{t+1})]}_{\text{fiscal capacity}} - \underbrace{\rho}_{\text{safe haven}}$$

- The first term works through outright default risk or through inflation risk
- Fiscal terms positive, safe haven negative: β_t has the sign of their difference

Notation

Two channels

The bond's equity beta

$$\beta_t \equiv \frac{\mathrm{Cov}_t(\log q_{t+1},\, \log p_{t+1})}{\mathrm{Var}_t(\log p_{t+1})}$$

has the sign of the stock-bond correlation ρ_t^{sb}.

Propositions 1 and 2 (fiscal dominance adds a third term, $\Phi(z_t)$)

$$\beta_t = \underbrace{\mathbb{E}_t[(1-\xi_{t+1})\,\Theta_{t+1}\,(1+\tau Y_{t+1}/B_{t+1})]}_{\text{fiscal capacity}} - \underbrace{\rho}_{\text{safe haven}}$$

- The first term works through outright default risk or through inflation risk
- Fiscal terms positive, safe haven negative: β_t has the sign of their difference

Notation

Two channels

The bond's equity beta

$$\beta_t \equiv \frac{\mathrm{Cov}_t(\log q_{t+1},\, \log p_{t+1})}{\mathrm{Var}_t(\log p_{t+1})}$$

has the sign of the stock-bond correlation ρ_t^{sb}.

Propositions 1 and 2 (fiscal dominance adds a third term, $\Phi(z_t)$)

$$\beta_t = \underbrace{\mathbb{E}_t[(1-\xi_{t+1})\,\Theta_{t+1}\,(1+\tau Y_{t+1}/B_{t+1})]}_{\text{fiscal capacity}} - \underbrace{\rho}_{\text{safe haven}}$$

- The first term works through outright default risk or through inflation risk
- Fiscal terms positive, safe haven negative: β_t has the sign of their difference

Notation

The prediction

Proposition 3: β_t rises with the forward interest expense

$$\beta_t \approx a_0 + a_1 \frac{(1 + i_t^n) B_t^n}{Y_t^n}, \qquad a_1 > 0$$

- **In words:** comovement rises with the interest bill relative to fiscal capacity ($\propto$ GDP)
- **Both regimes:** default under monetary dominance, inflation under fiscal dominance
- **Hence:** the correlation changes sign at most once, from negative to positive

The prediction

Proposition 3: β_t rises with the forward interest expense

$$\beta_t \approx a_0 + a_1 \frac{(1 + i_t^n) B_t^n}{Y_t^n}, \qquad a_1 > 0$$

- **In words:** comovement rises with the interest bill relative to fiscal capacity ($\propto$ GDP)
- **Both regimes:** default under monetary dominance, inflation under fiscal dominance

- **Annual, the horse race:** monthly returns in each year since 1960; 1,757 country-years
- **44 countries:** national equity index and 10-year zero-coupon government bond

How it is computed | Why a correlation

Bond yields: the data work

- Published curves: GSW (US), Bank of England (UK), BIS or Bloomberg
- Fourteen countries: Nelson-Siegel fits to vendor par yields
- Sparse grids: the vendor's converted benchmark quote
- 29 of the 44 bond series spliced, always on returns

Conclusion

From model to data

Model		**Data**
$\dfrac{(1+i_t^n)\,B_t^n}{Y_t^n}$	$\Longrightarrow$	$\text{ie}_{i,t}^{\text{fw}} = \dfrac{D_{i,t}}{Y_{i,t}} \cdot \dfrac{y_{10,i,t}}{100}$

What it measures

- The interest bill if the whole debt stock were refinanced at today's yield
- Realized payments carry old rates and respond to news only as debt rolls over

> *"[F]iscal sustainability cannot be assessed by traditional debt-to-GDP ratios but should instead be understood with measures like nominal or real interest as a share of GDP."*
>
> Furman and Summers (2020, p. 9)

How we build it

- Debt: the last published annual ratio (IMF); the yield: the 10-year zero-coupon yield
- Every regressor is lagged one period, so each regressor is predetermined

Just yields?

From model to data

Model		**Data**
$\dfrac{(1+i_t^n)\,B_t^n}{Y_t^n}$	$\Longrightarrow$	$\text{ie}_{i,t}^{\text{fw}} = \dfrac{D_{i,t}}{Y_{i,t}} \cdot \dfrac{y_{10,i,t}}{100}$

From model to data

Model		**Data**
$\dfrac{(1+i_t^n)\,B_t^n}{Y_t^n}$	$\Longrightarrow$	$\text{ie}_{i,t}^{\text{fw}} = \dfrac{D_{i,t}}{Y_{i,t}} \cdot \dfrac{y_{10,i,t}}{100}$

What it measures

- The interest bill if the whole debt stock were refinanced at today's yield
- Realized payments carry old rates and respond to news only as debt rolls over

> *"[F]iscal sustainability cannot be assessed by traditional debt-to-GDP ratios but should instead be understood with measures like nominal or real interest as a share of GDP."*
>
> Furman and Summers (2020, p. 9)

How we build it

- Debt: the last published annual ratio (IMF); the yield: the 10-year zero-coupon yield
- Every regressor is lagged one period, so each regressor is predetermined

Just yields?

Country FE	No	Yes	Yes	Yes
Month FE	No	Yes	Yes	Yes
Obs.	11,802	11,802	10,815	7,662

Monthly 10-year correlation; index and article count lagged one month. Two-way clustered SE (country, month) in parentheses. *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$. Columns as numbered in the paper.

The baseline exercise; salience and article count lagged, controls in the same month.

- **Baseline, 0.101:** a within SD of salience raises the correlation by 0.016, six percent of its within SD.
- **Without 2008 and 2009:** 0.094; the crisis alone does not drive it.
- **From 2010:** 0.056, about half.

Full table

Is it just yields?

The worry: the yield in ie^{fw} also moves with monetary policy, inflation and term premia.

- **Yield level or monetary stance?** Details
  - The policy rate leaves the estimate unchanged
  - Within countries, only the default-risk part of the yield matters
  - Fiscal news read from text predicts the correlation, most where debt is high
- **A common monetary regime?** (Campbell, Pflueger, and Viceira 2020) Details
  - Countries are compared within the same period, so what they share drops out
  - Euro area: one monetary regime, yet the periphery diverges after a fiscal shock
- **Each country's own credibility?** (Du, Pflueger, and Schreger 2020) Details
  - Country fixed effects absorb permanent differences
  - Euro area: credibility is shared, and the periphery still diverges
  - Outside the euro area, we do not separate fiscal dominance from weak credibility

Inflation

Is it just yields?

The worry: the yield in ie^{fw} also moves with monetary policy, inflation and term premia.

- **Yield level or monetary stance?** Details
  - The policy rate leaves the estimate unchanged
  - Within countries, only the default-risk part of the yield matters
  - Fiscal news read from text predicts the correlation, most where debt is high
- **A common monetary regime?** (Campbell, Pflueger, and Viceira 2020) Details
  - Countries are compared within the same period, so what they share drops out

Rating actions

Channels

Conclusion

Robustness

Is it inflation or the monetary regime?	Inflation
Is it one country?	Leave one out
Is it the early, thin panel?	Later samples
Does the association run the other way?	Timing
Is it the data cleaning?	Screens off
Why a correlation and not a beta?	Outcomes
Other measures of fiscal stress, other maturities?	Sweeps
Does the language model know the outcome?	Text checks
Does the yield already price the fiscal news?	Horse race

Conclusion

The hedge of government bonds depends on fiscal capacity: it is uneven and fragile.

- Bonds hedge where the interest bill is low and move with equities where it is high
- This holds across and within countries, in the euro area, in fiscal news and in rating actions
- Within countries, it runs through the compensation for sovereign default risk
- The hedge is fragile: losing it can raise the yield, and a higher yield raises the interest bill

Conclusion

The hedge of government bonds depends on fiscal capacity: it is uneven and fragile.

- Bonds hedge where the interest bill is low and move with equities where it is high
- This holds across and within countries, in the euro area, in fiscal news and in rating actions

- Within countries, it runs through the compensation for sovereign default risk
- The hedge is fragile: losing it can raise the yield, and a higher yield raises the interest bill

Appendix

Why persistent shocks

$$Y_{t+1} = Y_t \exp(g + \rho\sigma\varepsilon_t + \sigma\varepsilon_{t+1}), \qquad \varepsilon_t \sim \mathcal{N}(0,1) \text{ i.i.d.}$$

$$\log(1 + r_t) = -\log\delta + g + \rho\sigma\varepsilon_t - \tfrac{1}{2}\sigma^2$$

- ρ: persistence of the productivity shock in expected growth
- The real rate responds to the shock only through $\rho\sigma$
- In Proposition 1 the safe-haven term is $-\rho$: with $\rho = 0$ there is no safe-haven term
- Appendix A: the same propositions with Epstein-Zin, levered equity, a convenience flow

◁ Back

Model notation

Default threshold, as in the paper

$$z_t \equiv \frac{1}{\sigma}\left[\log\left(\frac{1+i_t^n}{1+\bar{\pi}}\frac{B_t\,(1-\delta)}{\lambda\,\tau\,Y_t}\right) - g - \rho\sigma\varepsilon_t\right]$$

Default-state value

$$\Theta_t = \frac{\Phi(z_t)}{\exp(\sigma z_t + \sigma^2/2)\left(1-\Phi(z_t+\sigma)\right)}$$

- Θ_t: value of the bond's payoff in default states relative to its value without default
- Φ: standard normal CDF; default has probability $\Phi(z_t)$, risk-neutral $\Phi(z_t+\sigma)$
- λ: share of fiscal capacity repaid in default, $1-\delta < \lambda < 1$; i_t^n: nominal rate
- β_t covers every state at $t+1$; the factor $1-\xi_{t+1}$ drops those with a default at $t+1$
- Default risk enters through q_{t+1}, the price of the new bond, which prices default at $t+2$

◁ Back

Fiscal dominance

Lemma 1 (common trigger): the debt coming due exceeds what the government can repay, $L_t > \lambda A_t$

Monetary dominance

- The government defaults and repays λA_t
- Inflation stays at its target

Fiscal dominance

- No default: full nominal repayment
- The price level rises until it is worth λA_t

Bondholders get the same real payoff in both regimes: same nominal price, debt and threshold z_t.

Proposition 2 (fiscal dominance)

$$\beta_t = \underbrace{\mathbb{E}_t[(1-\xi_{t+1})\,\Theta_{t+1}\,(1+\tau Y_{t+1}/B_{t+1})]}_{\text{as in Proposition 1}} - \underbrace{\rho}_{\text{safe haven}} + \underbrace{\Phi(z_t)}_{\text{inflation}}$$

- With probability $\Phi(z_t)$ the trigger hits at $t+1$, and the price level rises as much as output falls
- The real bond price then falls with output: a third term, rising with forward interest expense
- Hence the slope a_1 of Proposition 3 is steeper than under monetary dominance

◁ Back

Computing the correlation

A plain Pearson correlation of the paired equity and bond returns inside one calendar window. A Fisher transformation appears only in the robustness tables.

- **Monthly (baseline):** daily returns in each calendar month; at least 15 paired trading days
- **Non-overlapping:** one value per country and month; no regression uses a rolling window
- **Calendar:** each country's own trading calendar, so no pair spans a market holiday
- **Missing days:** left empty, never carried forward, which would fake a zero bond return
- **Returns:** daily log equity return; bond $-n\,\Delta y/100$ on the 10-year zero-coupon yield, $n = 10$
- **Annual (horse race):** monthly returns in each calendar year; at least 10 of 12 months
- **Annual bond return:** with carry, $y_{s-1}/12 - n\,\Delta y_s$
- **Why monthly returns there:** they reach 1960, giving 1,788 country-years against 1,225
- **Event study:** three-month bins from 20 October 2009; at least 40 trading days per bin
- **Countries:** 44, of which 29 advanced economies and 15 emerging markets

◁ Back

Why a correlation

The propositions are stated on the bond's equity beta, which has the sign of the correlation.

- The beta is the correlation times the volatility of bond returns relative to equity returns
- That relative volatility differs severalfold across countries and moves over time
- The correlation measures the comovement alone and is bounded
- A constant rescaling of either return leaves the correlation unchanged and moves the beta
- The correlation is the measure used in much of the literature on stock-bond comovement

Nested cumulative samples, all 44 countries in each. Two-way clustered SE (country, month). *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$.

- The within estimate is positive and significant in every column
- It is larger on the 2015 sample: 0.032 against 0.014 on the full sample
- The slope across country averages is stable, between 0.044 and 0.051

◁ Back ◁ Robustness

Yield level or monetary stance?

The account: ie^{fw} is the yield with a label: its link to the correlation comes from the monetary policy and term premium in the yield.

How it could produce our result: the debt ratio changes once a year, so month to month ie^{fw} moves with the yield.

What answers it:

- **Annual horse race:** the yield should take over; ie^{fw} keeps 0.0131 and the yield drops to 0.0038
- **Policy rate added:** the estimate should fall; it is unchanged at 0.0137
- **Yield split via CDS, within countries:** the non-default share should load; it is -0.0100 (0.0110), against 0.055 for credit; difference $p = 0.007$
- **Inflation-linked split, within countries:** the real yield or breakeven should load; neither does, while credit gives 0.139
- **News sorted on debt:** fiscal news should add nothing; it predicts the correlation, most in the top debt bin (0.200); equal slopes rejected, $p = 0.0007$
- **Reverse timing:** the lagged correlation should predict ie^{fw}; on the annual panel it does not

◁ Back

A common monetary regime?

The account: the sign follows the mix of supply and demand shocks, which decides whether inflation rises or falls in bad times, and how the central bank reacts (Campbell, Sunderam, and Viceira 2017; Song 2017; Campbell, Pflueger, and Viceira 2020; Bauer, Pflueger, and Sunderam 2024; Pflueger 2025).

How it could produce our result: debt and yields share its trends. The hedge appeared as yields fell in the 1990s and weakened as debt and yields rose after 2020.

What answers it:

- **Same-period comparison:** every estimate compares countries in the same period, so any common driver drops out
- **Euro area:** one monetary regime, which the periphery-core comparison differences out; the gap still rises by 0.44 ($p = 0.002$)
- **Yield components:** month fixed effects remove the common half of the non-default share's within-country variance, and the real-yield and breakeven estimates left by country fixed effects
- **Complements:** the monetary regime sets what all countries share; the burden says which country moves

What remains: the time-series evidence, and a common shock that hits high-burden countries harder.

◁ Back

Each country's own credibility?

The account: weak monetary credibility makes inflation countercyclical, so local-currency bonds fall with stocks (Du, Pflueger, and Schreger 2020).

How it could produce our result: credibility differs across countries and over time. Without country fixed effects inflation has a positive coefficient (0.0073); across countries every yield component predicts the correlation.

What answers it:

- **Country fixed effects:** they absorb permanent differences in credibility
- **Euro area:** one central bank and one target, yet the periphery-core gap rises by 0.44 ($p = 0.002$)
- **Inflation-linked split, within countries:** breakeven does not load (-0.0308, 14 countries); credit does (0.139)
- **Source of the credit result:** the euro periphery, 84 percent of the within-country variation, where credibility is common
- **Complementary:** in our model, inflation in bad states is the fiscal-dominance route; their credibility proxy is the press discussing a country's debt and inflation together

What remains: outside the euro area, we do not separate fiscal dominance from weak credibility.

◁ Back

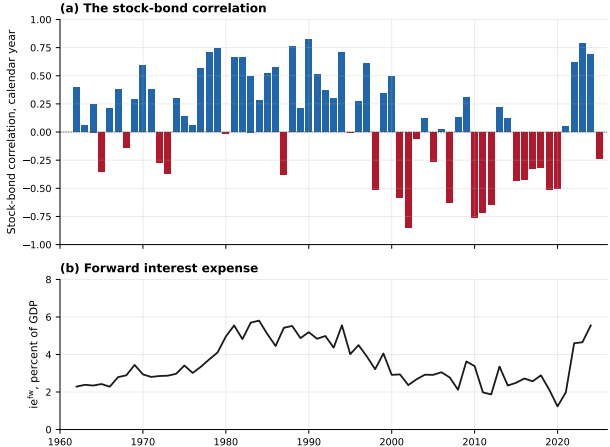

Inflation

Samples and placebo dates

Paper Figure C.5, remaining rows; the reported estimate repeated at the top.

◁ Back

Building the index: classification

- **Corpus:** Factiva dump of the Wall Street Journal, 200,391 articles from January 2000
- **Prefilter:** a country alias, a regional keyword (EU, IMF, ECB) or a fiscal keyword; 174,802 kept
- **Model:** Kimi K2.5 on the Fireworks Batch API, temperature 0, prompt v1.4
- The 11,170 articles added by the repaired alias table: Kimi K2.6, same prompt

The question (prompt v1.4): *"Determine whether the article substantively discusses sovereign fiscal sustainability for one or more countries. 'Substantively' means the article dedicates at least one full sentence to the sovereign's fiscal position."*

- **Ambiguity rule:** *"When in doubt, err on the side of NOT flagging."*
- **Output:** the fiscal flag, eight fiscal topics (A to H), verbatim evidence, the countries named
- **Exclusions:** sub-national governments; vague groups ("emerging markets") do not qualify

Source: replication package, generation code for the index (prompt, configuration, prefilter, attribution specification).

Attribution | ◁ Back

Building the index: attribution

- **Model:** Kimi K2.6, pinned weights revision, self-hosted (vLLM), temperature 0, one call per article
- **The question:** which panel countries the article substantively discusses,
  "at least one full sentence about that country's economy, government, public finances, markets or affairs"
- Asked of every article, flagged or not: numerator and denominator share one attribution rule
- **Index:** flagged share of the articles attributed to the country, per month; lagged one month
- **Control:** $\log(1 + \text{article count})$ in every specification
- **Variants:** alias-confirmed pairs; a numerator bound to the country the fiscal discussion is about
- **Records:** every run logged in a run index; a seed registry for every stochastic step

Examples. Flagged: *"U.K. Deficit Worries Hit Government Debt"*
Not flagged: *"Toyota, Yen Hit Shares In Japan"*

Source: the package's attribution specification, configuration and run records; headlines from the anonymization probe sample.

◁ Back

All validation checks

- **Anonymization:** same classifier and prompt on text with names, currencies, officials, institutions and dates replaced; article-level kappa 0.86, country-month shares correlate at 0.88
- The slope falls from 0.075 to 0.049 and keeps its sign; identifiers survive in 24.7 and 35.4 percent
- **Negativity:** beside Loughran-McDonald negativity of the same articles, the index keeps 0.093
- **Policy uncertainty:** on the nineteen EPU countries, adding EPU moves 0.260 to 0.256
- **Attention placebo:** 0.003 on the correlation with US equity, against 0.105 on stock-bond
- **Attribution:** 7.2 percent of pairs carry no alias; alias-confirmed pairs alone give 0.095
- **Thin shares:** at least two, three, five articles: 0.151, 0.188, 0.283

CDS and inference

- Markit composite, senior unsecured, five years; in dollars (euros for the US)
- Dollar spreads also price a quanto component and, in the euro area, redenomination
- Lagged spreads above 1,000 basis points are dropped: 34 rows, 26 of them Greek
- Tighter cuts raise the credit coefficient: 0.10 at 500 and 0.14 at 200 basis points
- Wild cluster restricted bootstrap-t by country, 9,999 draws
